

How branch synchrony changes mixture variation

Grey: individual variance terms. Orange: positive covariance. Teal: negative covariance. Black: resulting mixture variance.

Weights are each window's mean flow shares. $\text{Var}(\text{mix}) = w^2 \text{Var}(A) + (1-w)^2 \text{Var}(B) + 2w(1-w) \text{Cov}(A,B)$.
This decomposes coeval observed concentrations and branch synchrony; it does not estimate propagation lag.
