

Later flow peaks and DOC buffering are distinct questions

One nested reach, 422 paired hours. All segments retained; hours and windows are not independent catchments.

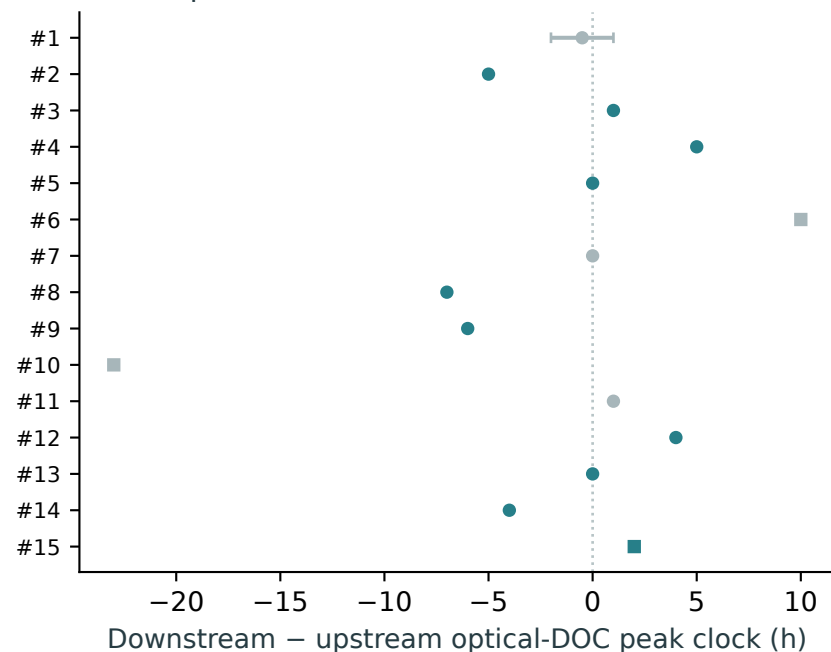

a Seven long segments: later flow maxima

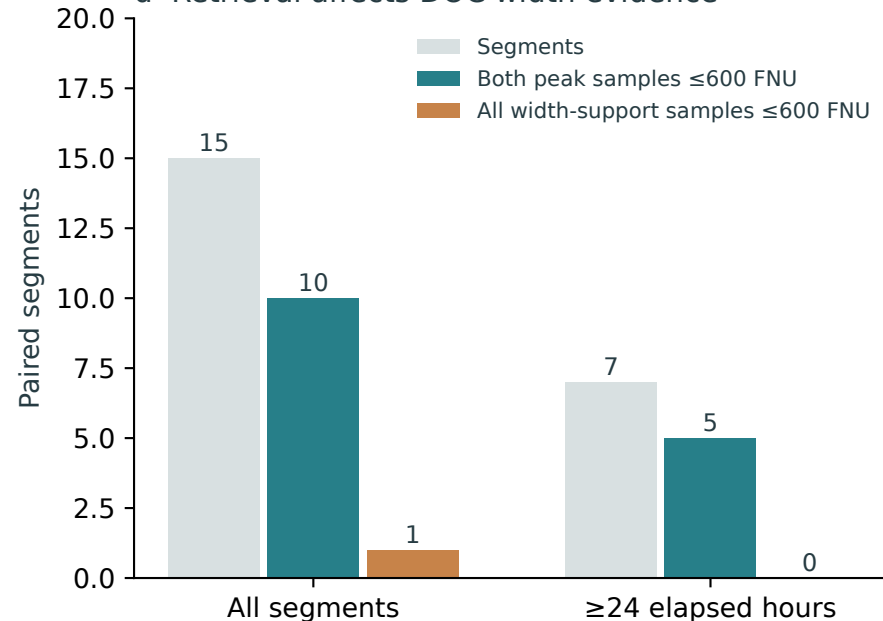

b Later arrival is not wider duration

c DOC peak clocks do not share one offset

d Retrieval affects DOC width evidence

Peak clocks have 1-h resolution; widths interpolate adjacent samples only. c: Squares mark multiple author events; grey marks >600-FNU peaks. DOC above 600 FNU uses flow/rainfall regressions; lower-turbidity DOC is still a corrected optical estimate. Width support includes crossing samples. All DOC maxima exceed the source laboratory calibration maximum of 3.88 mg C/L; the turbidity screen does not validate their accuracy.
