

Real confluences: how incoming water waves overlap

All 20 original spring windows retained; 12 have $\geq 95\%$ joint coverage and preserve site maxima. These are not 20 independent storms.

Flow is stage-derived at 30-min resolution; peak-clock differences are not hydraulic travel times. a: Bars span tied sampled maxima. b: Same-clock comparison without lag search. c: Incoming-signal combination, not observed outlet attenuation. DOC is neither filled nor inferred from flow.
